The ASUMA traverse

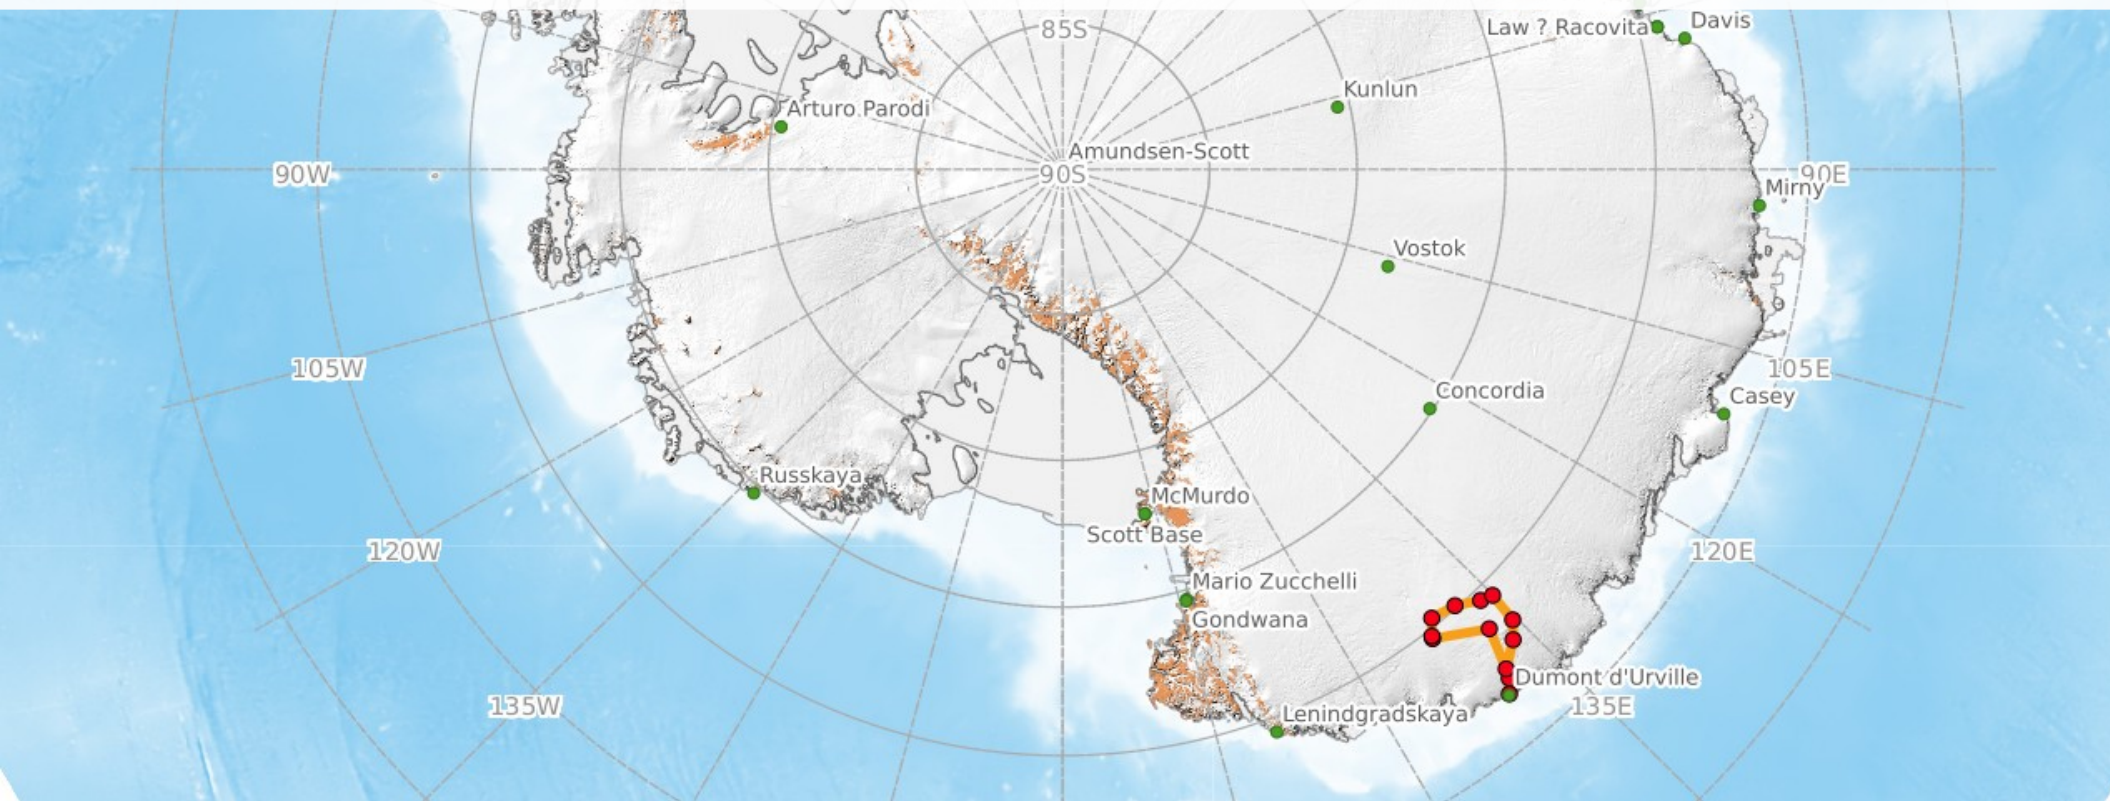

Context: International Trans Antarctic Scientific Expedition (ITASE)

Objective: refine **Surface Mass Balance** estimates and related processes in the “transition zone”

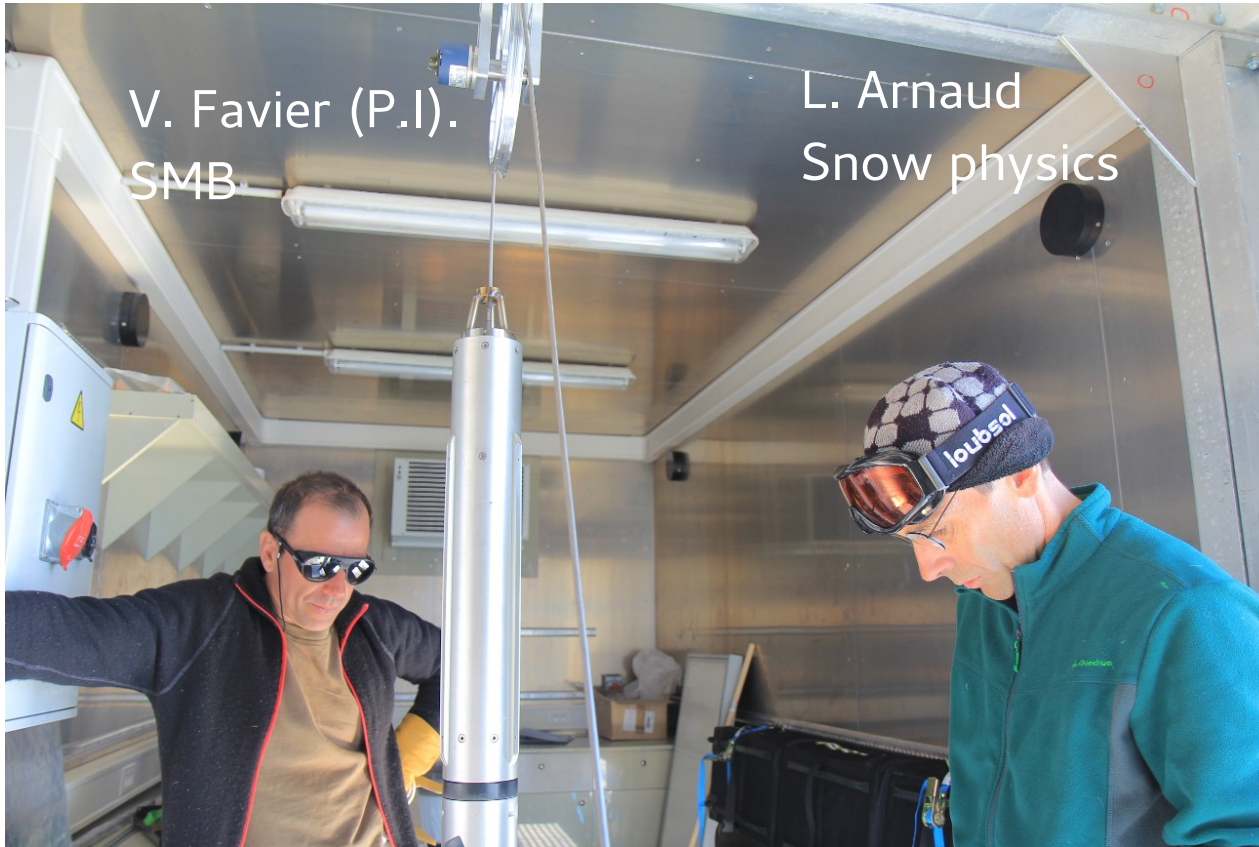

Transition zone is between

- the coastal regions: accumulation 500-1000+ mm, many stations
- the domes and the high East-Antarctic plateau: accumulation 20-50mm, a few stations

No station → accessible by traverse only.

The road

The road

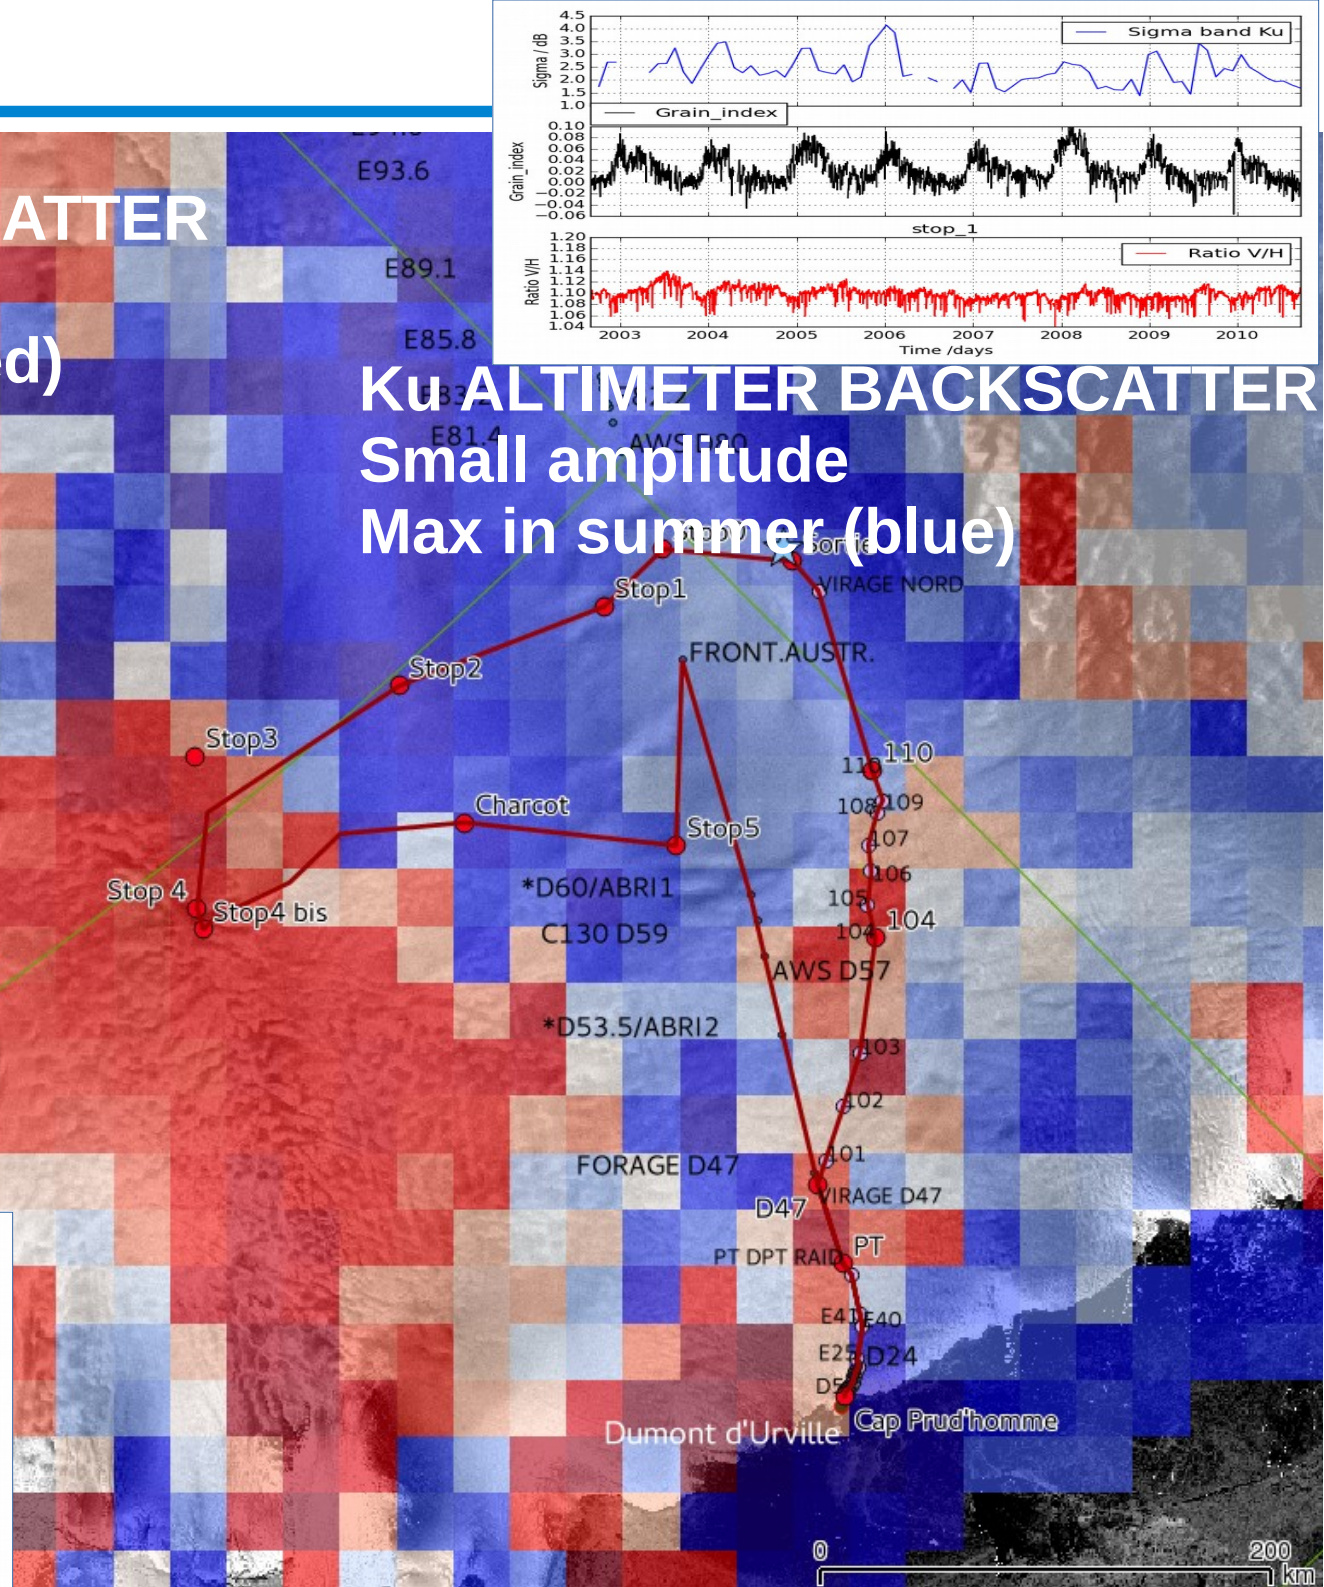

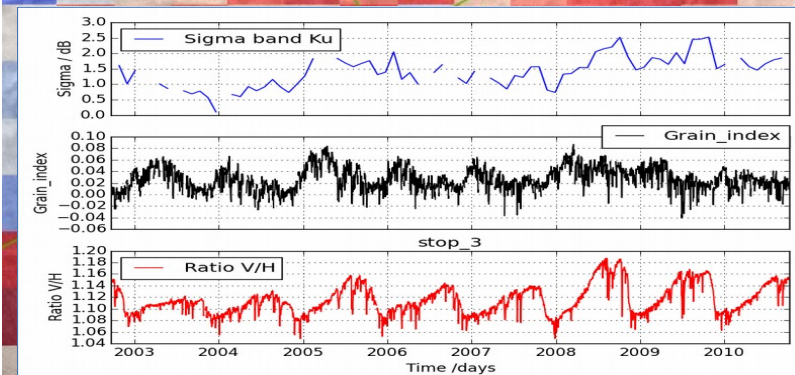

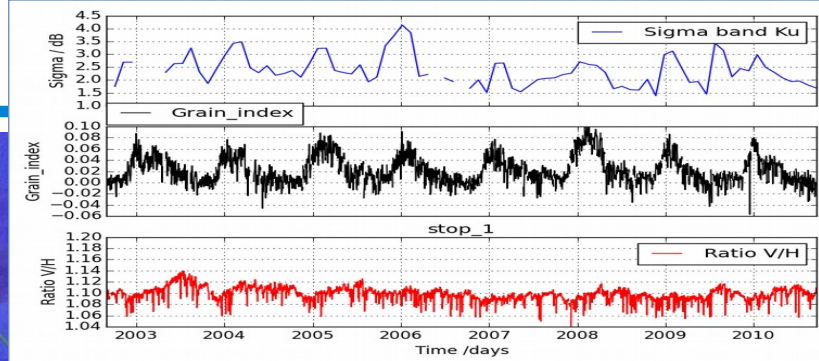

The road

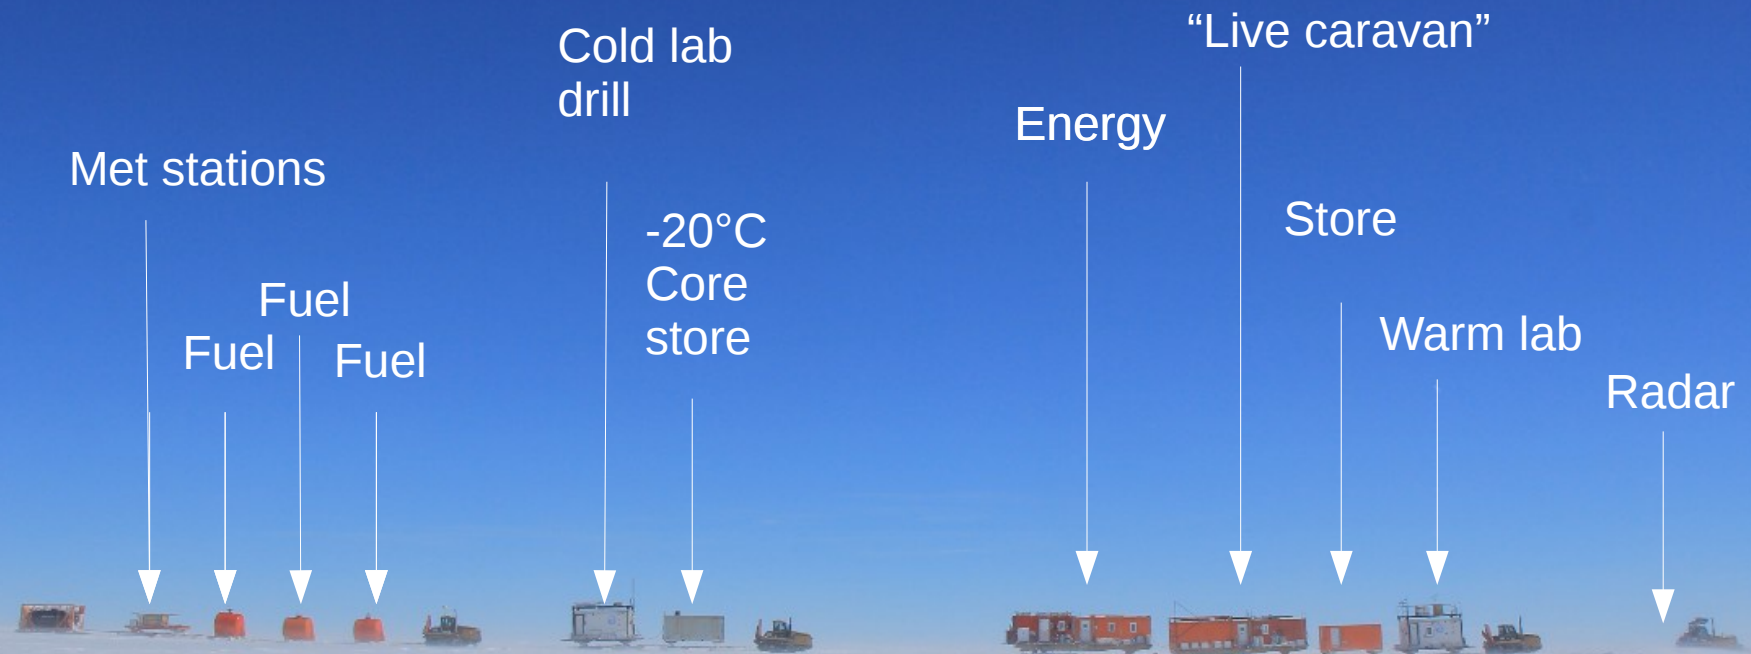

The road

Ku ALTIMETER BACKSCATTER
Large amplitude
Max in autumn/winter (red)

Ku ALTIMETER BACKSCATTER
Small amplitude
Max in summer (blue)

The logistics

The observations

Setup of nearly 50 stacks along the traverse (~every 25-40 km)
hoping to revisit them to measure the local accumulation

The observations

Relative accumulation measurements with GPR along the 1300km of the traverse

The observations

Additional 400km of transects around the stops

→ Huge kilometer-scale variations of the accumulation, related with the topography.

The observations

Absolute accumulation (radiochemistry), origin of precipitation (isotopes, ions)
, ... from firn cores

Mini-felics: 20m in 2h

Felics: 50m in 1.5 days

The observations

We have collected 25 cores at 16 sites, or 580m of firn

The observations

Roughness measurements: OSUG laserscan

35 scans at 25 locations

The observations

Scan at STOP3

15m

The observations

Roughness measurements: home-made rugged laser scan

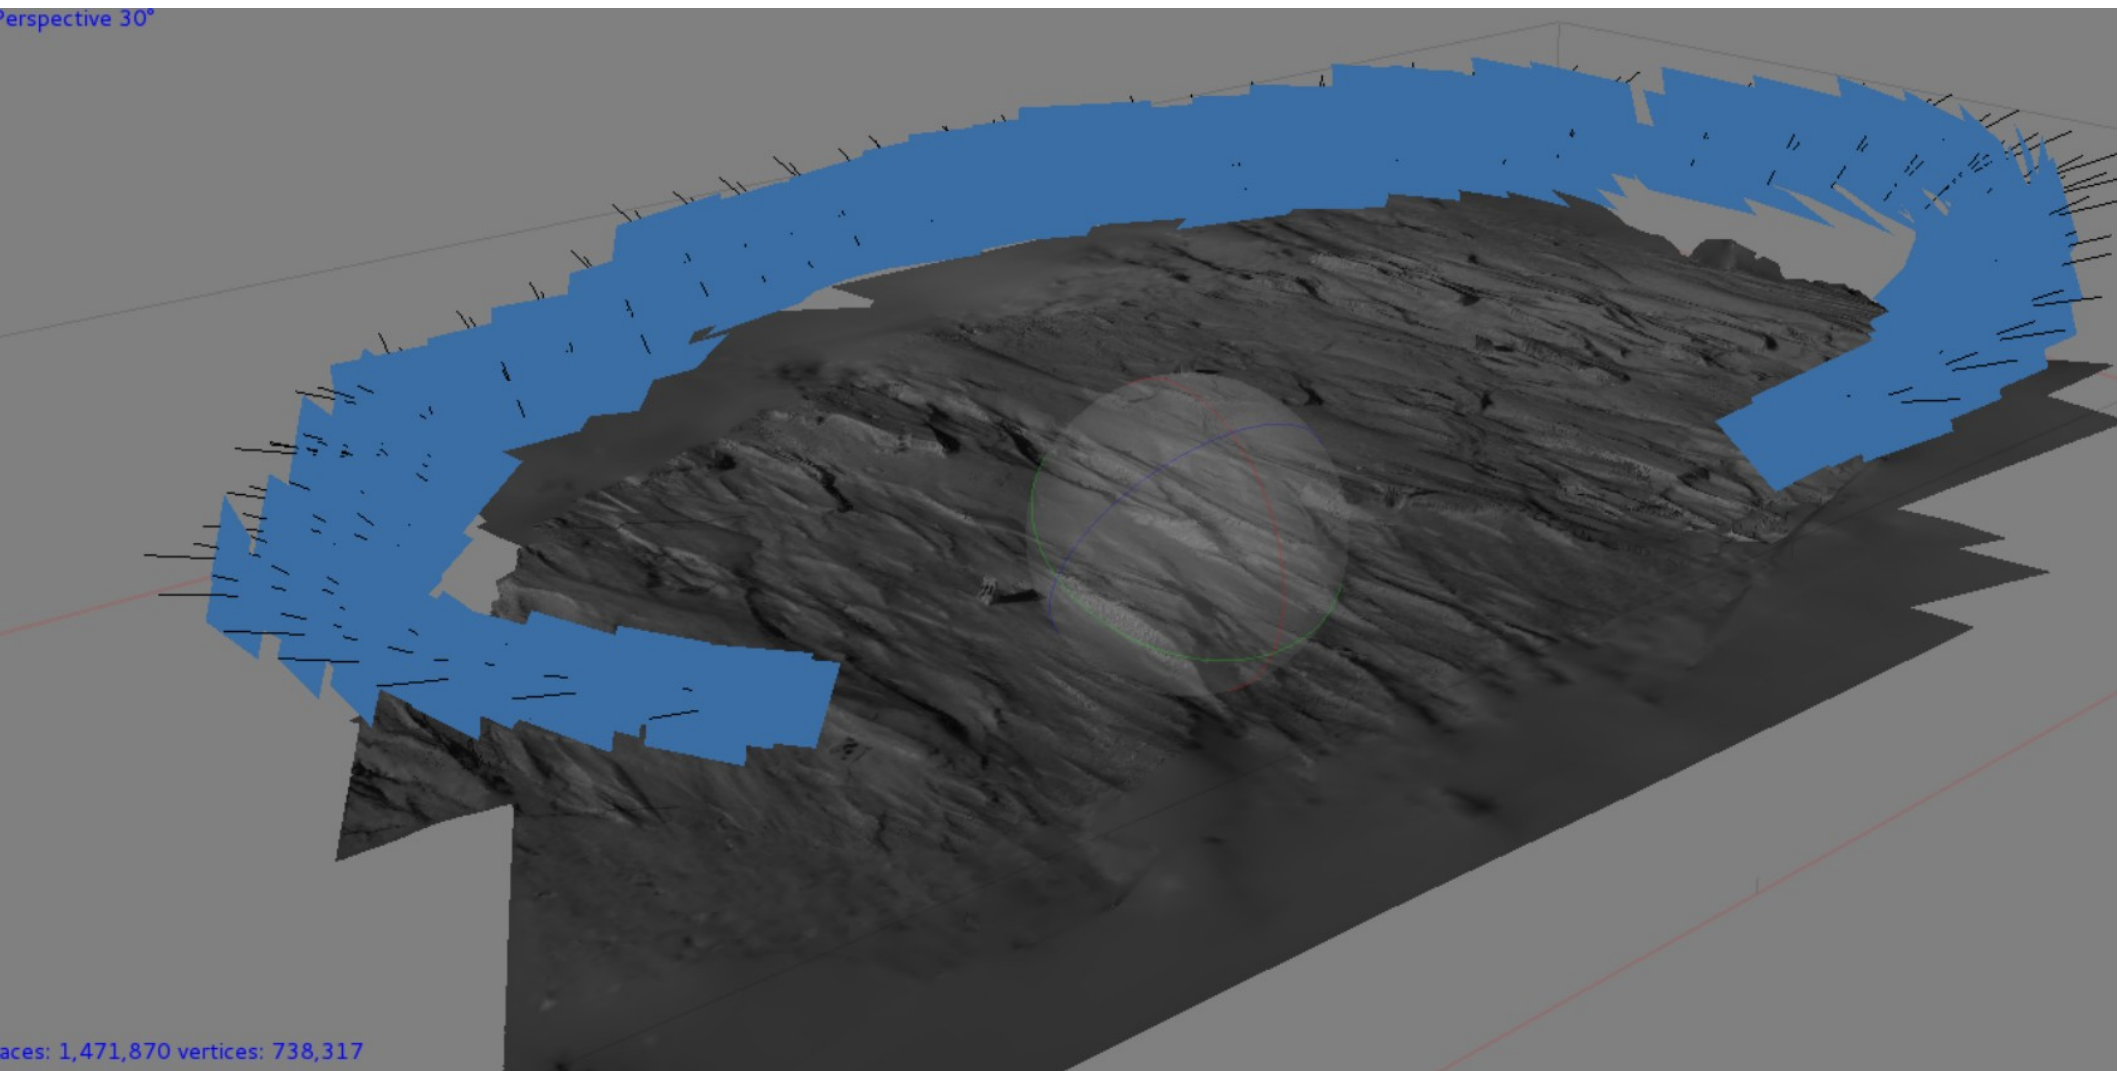

The observations

Roughness measurements: multiphotography and dense correlation processing
(Photoscan software)

The observations

Roughness measurements: multiphotography and dense correlation processing
(Photoscan software)

The observations

Spectral albedo measurements at every stop

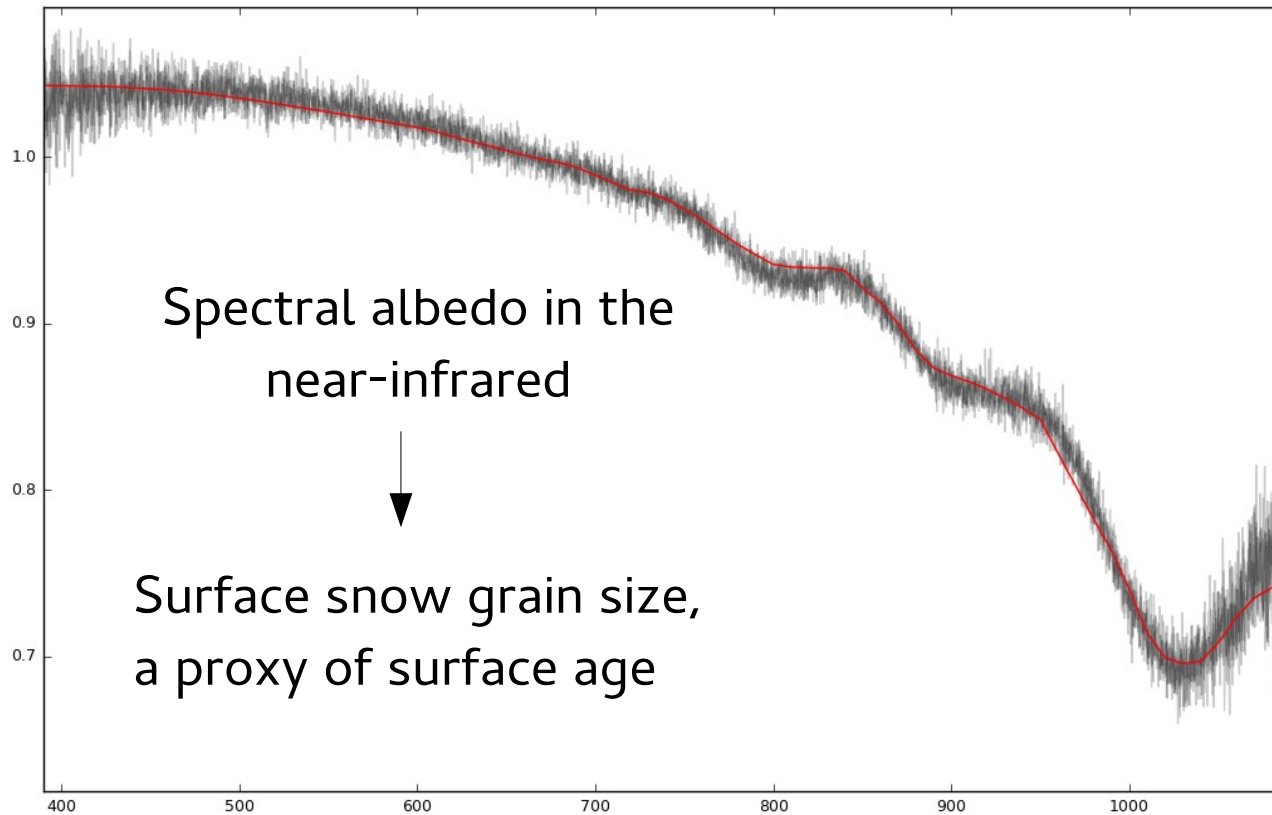

The observations

at every stop... 300 spectra collected.

The observations

Maxim Lamare (CEN/IGE)

The observations

General snow physics observations

The observations

Snow physics: profiles of **grain size** and **density** over 8m

Volume+mass
measurements
every 10 cm

Optical grain size
measurements with ASSSAP

The observations

Snow physics: ~15 profiles of grain size and density of up to 8m

With training it takes 2h for two persons, extraction of the snow core, density and grain size processing

→ application to microwave modeling and snow evolution modeling (stage A. Lemoine)

The observations

Detailed study of dunes: ~20 points in 100m²

Surface elevation map

Micropenetrometer

Surface density

Spectral albedo

The observations

3 detailed studies of dunes

The observations

2 met stations at STOP0 (wet / smooth) and STOP4 (dry / rough)

- temperature, RH, wind at 5 levels
- flowcapt at 3 levels
- 4 snow depth rangers
- SW and LW up and down radiative fluxes
- VIS/NIR Spectroradiometer 7 bands
- Snow temperature profile up to 10m

The observations

Unfortunately, the solar panels on STOP4 station failed... the station is going to die

First scientific conclusions

- The annual accumulation varies at kilometer scale in very large proportion as a function of the small topographic changes
- High variability of surface roughness and types of roughnesses.

First scientific conclusions

- High variability of surface roughness and types of roughness (cont.)

First scientific conclusions

- High variability of surface roughness and types of roughness (cont.)

First scientific conclusions

Roughness is controlled by accumulation and wind/slope (e.g. Frezzotti et al.)

Accumulation/wind ratio: low medium high

Main conclusion

We have collected tons of data to work on!

It has been a great experience, opening our view on the diversity of surfaces
