## XiHe: A Data-Driven Model for Global Ocean Eddy-Resolving Forecasting

Xiang Wang, Renzhi Wang, Ningzi Hu, Pinqiang Wang, Peng Huo, Guihua Wang, Huizan Wang, Senzhang Wang, Junxing Zhu, Jianbo Xu, Jun Yin, Senliang Bao, Ciqiang Luo, Ziqing Zu, Yi Han, Weimin Zhang, Kaijun Ren, Kefeng Deng, Junqiang Song

**Abstract**—Global ocean forecasting is fundamentally important to support marine activities. The leading operational Global Ocean Forecasting Systems (GOFSs) use physics-driven numerical forecasting models that solve the partial differential equations with expensive computation. Recently, specifically in atmosphere weather forecasting, data-driven models have demonstrated significant potential for speeding up environmental forecasting by orders of magnitude, but there is still no data-driven GOFS that matches the forecasting accuracy of the numerical GOFSs. In this paper, we propose the first data-driven  $1/12^\circ$  resolution global ocean eddy-resolving forecasting model named *XiHe*, which is established from the 25-year France Mercator Ocean International's daily GLORYS12 reanalysis data. *XiHe* is a hierarchical transformer-based framework coupled with two special designs. One is the land-ocean mask mechanism for focusing exclusively on the global ocean circulation. The other is the ocean-specific block for effectively capturing both local ocean information and global teleconnection. Extensive experiments are conducted under satellite observations, *in situ* observations, and the IV-TT Class 4 evaluation framework of the world's leading operational GOFSs from January 2019 to December 2020. The results demonstrate that *XiHe* achieves stronger forecast performance in all testing variables than existing leading operational numerical GOFSs including Mercator Ocean Physical System (PSY4), Global Ice Ocean Prediction System (GIOPS), BLUEinK OceanMAPS (BLK), and Forecast Ocean Assimilation Model (FOAM). Particularly, the accuracy of ocean current forecasting of *XiHe* out to 60 days is even better than that of PSY4 in just 10 days. Additionally, *XiHe* is able to forecast the large-scale circulation and the mesoscale eddies. Furthermore, it can make a 10-day forecast in only 0.36 seconds, which accelerates the forecast speed by thousands of times compared to the traditional numerical GOFSs.

**Index Terms**—Global Ocean Forecasting, Deep Learning, Eddy Resolving, Data-Driven, AI for Science

### 1 INTRODUCTION

Ocean forecasting is critically important for many marine activities. At present, the leading GOFSs (e.g. Mercator Ocean Physical System (PSY4) and Real-Time Ocean Forecast System (RTOFS)) use physics-driven models in fluid mechanics and thermodynamics to predict future ocean motion states and phenomena based on current ocean conditions [1]. The GOFSs adopt numerical methods that rely on supercomputers to solve the partial differential equations of the physical models. Due to their desirable performance, they are operationally run in different countries worldwide. However, numerical forecasting methods are usually computationally expensive and slow. For example, a single forecasting simulation in the numerical GOFSs may take hours on a supercomputer with hundreds of computational nodes [2]. Besides, improving the forecasting accuracy of these methods is exceedingly challenging because they heavily rely on the human cognitive abilities in understanding the physical laws of the ocean environment [3].

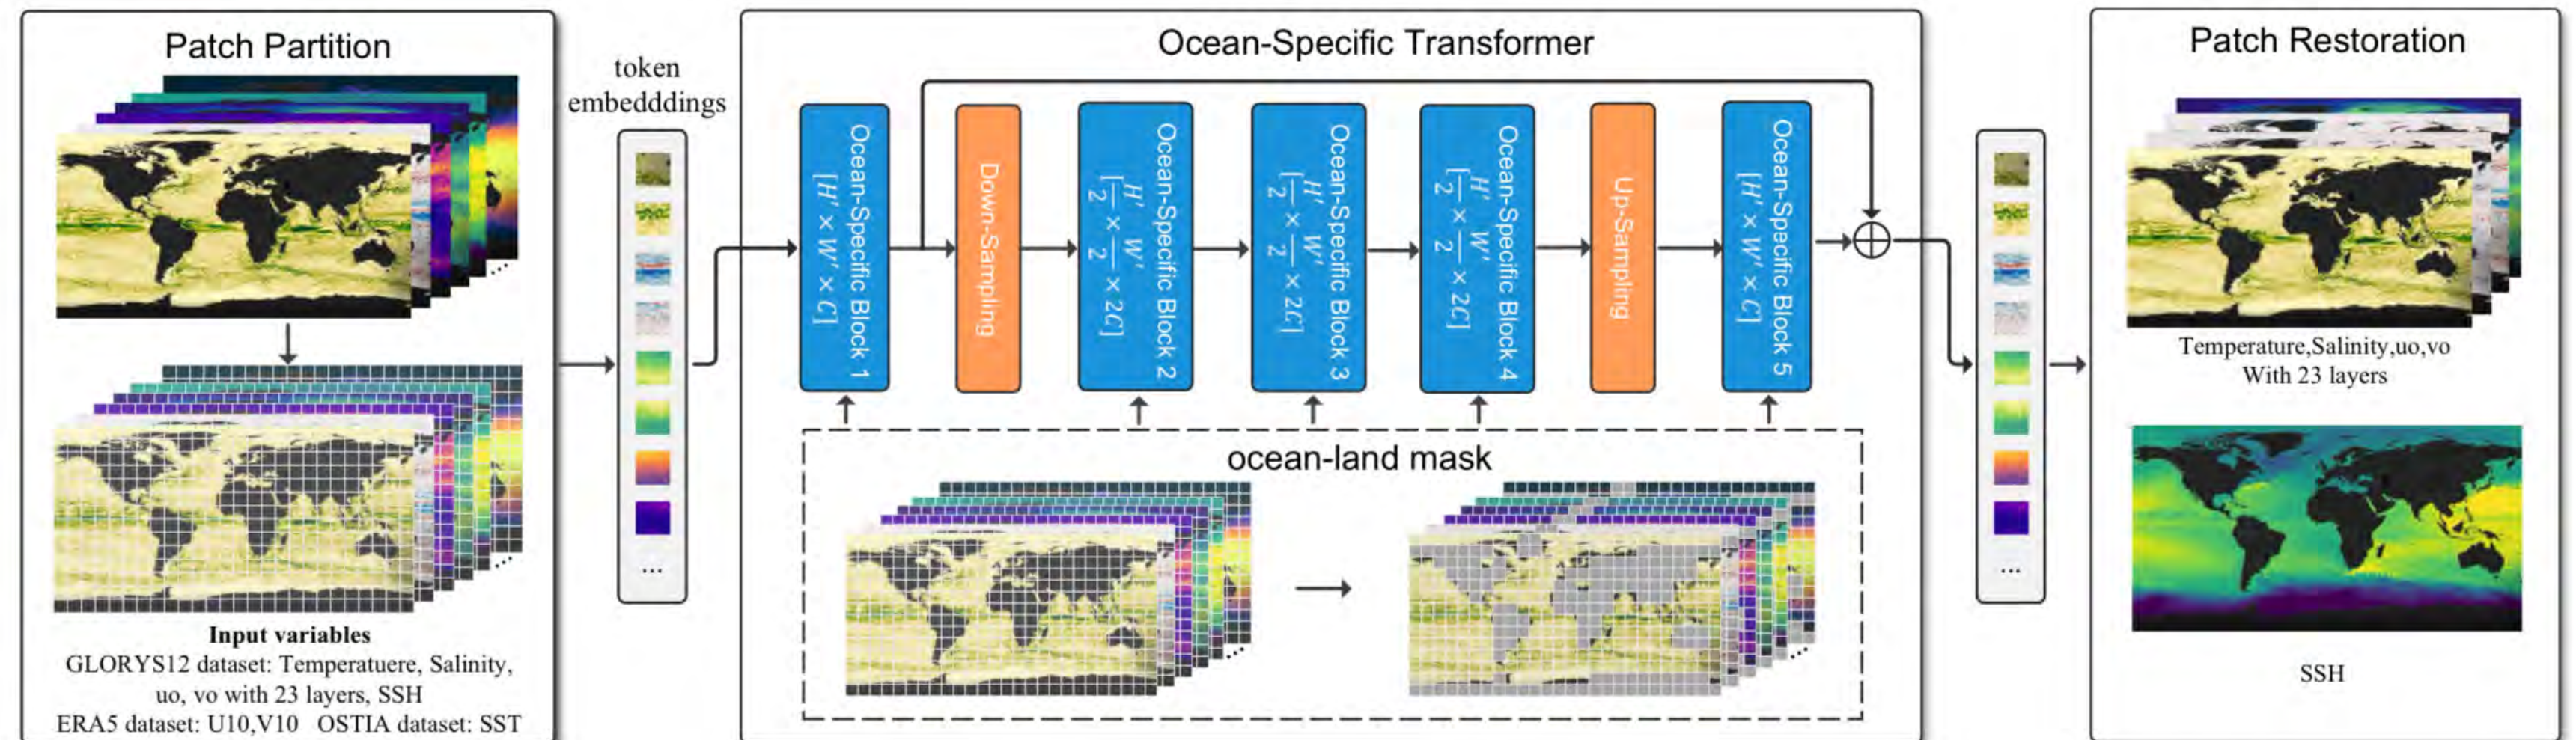

With the recent advances of Artificial Intelligence (AI) techniques, deep learning methods have been widely applied in various prediction/forecasting tasks of different fields and achieved great success. Particularly, some data-driven AI models have shown the potential in atmosphere weather forecasting like *Pangu-Weather* [4] and *GraphCast* [5]. They have achieved comparable or even better prediction results in global medium-range weather forecasting than current leading numerical weather prediction (NWP) methods [4, 5, 6, 7, 8, 9]. One significant advantage of data-driven models is that they can make the forecasting thousands or even tens of thousands of times faster than NWP methods [4]. Furthermore, they can automatically learn the spatial-temporal relationships from massive meteorological data, and effectively capture the rules of weather changing, without introducing the prior knowledge of physics mechanisms.

Although data-driven models have achieved promising results in atmosphere weather forecasting, how to build a more accurate and efficient data-driven ocean forecasting model remains an open research issue due to the following

Brenner<sup>1,6</sup> & Stephan Hoyer<sup>1,6</sup>

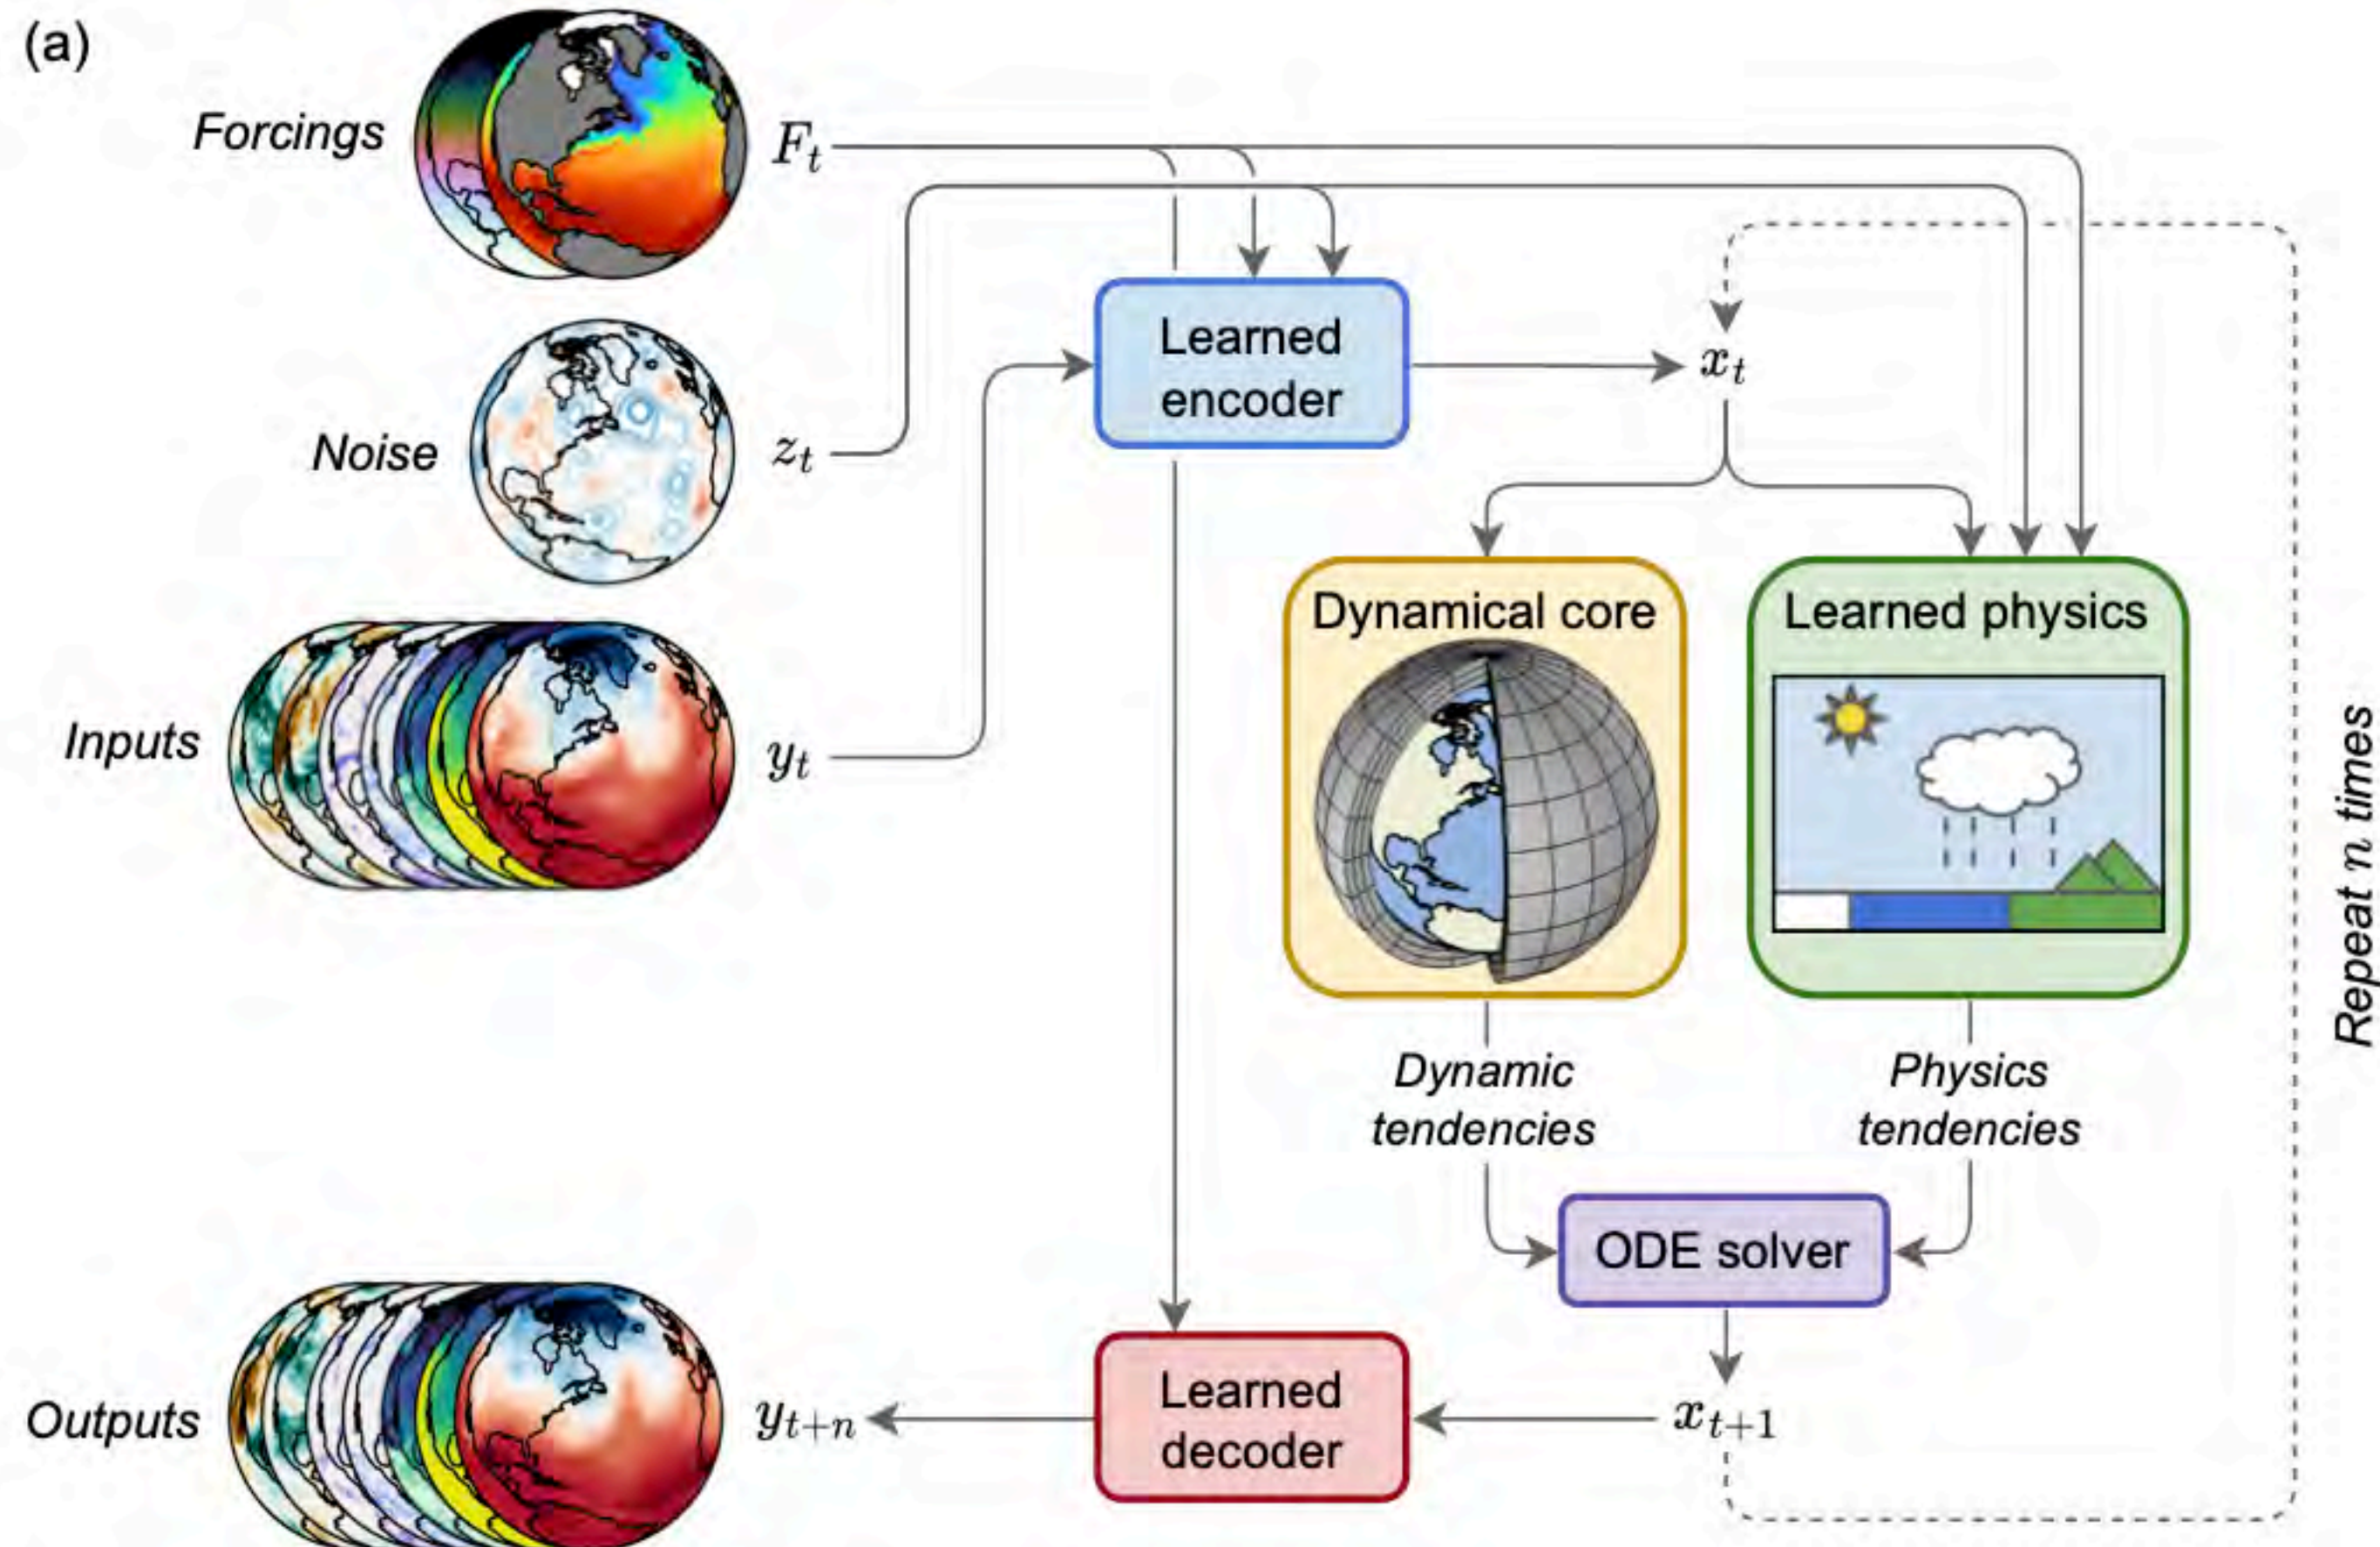

General circulation models (GCMs) are the foundation of weather and climate prediction<sup>1,2</sup>. GCMs are physics-based simulators that combine a numerical solver for large-scale dynamics with tuned representations for small-scale processes such as cloud formation. Recently, machine-learning models trained on reanalysis data have achieved comparable or better skill than GCMs for deterministic weather forecasting<sup>3,4</sup>. However, these models have not demonstrated improved ensemble forecasts, or shown sufficient stability for long-term weather and climate simulations. Here we present a GCM that combines a differentiable solver for atmospheric dynamics with machine-learning components and show that it can generate forecasts of deterministic weather, ensemble weather and climate on par with the best machine-learning and physics-based methods. NeuralGCM is competitive with machine-learning models for one- to ten-day forecasts, and with the European Centre for Medium-Range Weather Forecasts ensemble prediction for one- to fifteen-day forecasts. With prescribed sea surface temperature, NeuralGCM can accurately track climate metrics for multiple decades, and climate forecasts with 140-kilometre resolution show emergent phenomena such as realistic frequency and trajectories of tropical cyclones. For both weather and climate, our approach offers orders of magnitude computational savings over conventional GCMs, although our model does not extrapolate to substantially different future climates. Our results show that end-to-end deep learning is compatible with tasks performed by conventional GCMs and can enhance the large-scale physical simulations that are essential for understanding and predicting the Earth system.

Solving the equations for Earth's atmosphere with general circulation models (GCMs) is the basis of weather and climate prediction<sup>1,2</sup>. Over the past 70 years, GCMs have been steadily improved with better numerical methods and more detailed physical models, while exploiting faster computers to run at higher resolution. Inside GCMs, the unresolved physical processes such as clouds, radiation and precipitation are represented by semi-empirical parameterizations. Tuning GCMs to match historical data remains a manual process<sup>3</sup>, and GCMs retain many persistent errors and biases<sup>5–8</sup>. The difficulty of reducing uncertainty in long-term climate projections<sup>9</sup> and estimating distributions of extreme weather events<sup>10</sup> presents major challenges for climate mitigation and adaptation<sup>11</sup>.

Recent advances in machine learning have presented an alternative for weather forecasting<sup>3,4,12,13</sup>. These models rely solely on machine-learning techniques, using roughly 40 years of historical data from the European Centre for Medium-Range Weather Forecasts (ECMWF) reanalysis v5 (ERAS)<sup>14</sup> for model training and forecast initialization. Machine-learning methods have been remarkably successful,

demonstrating state-of-the-art deterministic forecasts for 1- to 10-day weather prediction at a fraction of the computational cost of traditional models<sup>3,4</sup>. Machine-learning atmospheric models also require considerably less code, for example GraphCast<sup>3</sup> has 5,417 lines versus 376,578 lines for the National Oceanic and Atmospheric Administration's FV3 atmospheric model<sup>15</sup> (see Supplementary Information section A for details).

Nevertheless, machine-learning approaches have noteworthy limitations compared with GCMs. Existing machine-learning models have focused on deterministic prediction, and surpass deterministic numerical weather prediction in terms of the aggregate metrics for which they are trained<sup>3,4</sup>. However, they do not produce calibrated uncertainty estimates<sup>4</sup>, which is essential for useful weather forecasts<sup>1</sup>. Deterministic machine-learning models using a mean-squared-error loss are rewarded for averaging over uncertainty, producing unrealistically blurry predictions when optimized for multi-day forecasts<sup>3,13</sup>. Unlike physical models, machine-learning models misrepresent derived (diagnostic) variables such as geostrophic wind<sup>16</sup>. Furthermore,

## Versatile Ocean Simulation in Pure Python

Veros, the versatile ocean simulator, aims to be the swiss army knife of ocean modeling. It is a full-fledged primitive equation ocean model that supports anything between idealized toy models and realistic, high-resolution, global ocean simulations. And because Veros is written in pure Python, the days of struggling with complicated model setup workflows, ancient programming environments, and obscure legacy code are finally over.

*In a nutshell, we want to enable high-performance ocean modelling with a clear focus on flexibility and usability.*

Veros supports a NumPy backend for small-scale problems, and a high-performance JAX backend with CPU and GPU support. It is fully parallelized via MPI and supports distributed execution on any number of nodes, including multi-GPU architectures (see also our benchmarks).

The dynamical core of Veros is based on pyOM2, an ocean model with a Fortran backend and Fortran and Python frontends.

If you want to learn more about the background and capabilities of Veros, you should check out A short introduction to Veros. If you are already convinced, you can jump right into action, and learn how to get started instead!

*... because the Baroque is over.*

General circulation models (GCMs) are the foundation of weather and climate prediction<sup>1,2</sup>. GCMs are physics-based simulators that combine a numerical solver for large-scale dynamics with tuned representations for small-scale processes such as cloud formation. Recently, machine-learning models trained on reanalysis data have achieved comparable or better skill than GCMs for deterministic weather forecasting<sup>3,4</sup>. However, these models have not demonstrated improved ensemble forecasts, or shown sufficient stability for long-term weather and climate simulations. Here we present a GCM that combines a differentiable solver for atmospheric dynamics with machine-learning components and show that it can generate forecasts of deterministic weather, ensemble weather and climate on par with the best machine-learning and physics-based methods. NeuralGCM is competitive with machine-learning models for one- to ten-day forecasts, and with the European Centre for Medium-Range Weather Forecasts ensemble prediction for one- to fifteen-day forecasts. With prescribed sea surface temperature, NeuralGCM can accurately track climate metrics for multiple decades, and climate forecasts with 140-kilometre resolution show emergent phenomena such as realistic frequency and trajectories of tropical cyclones. For both weather and climate, our approach offers orders of magnitude computational savings over conventional GCMs, although our model does not extrapolate to substantially different future climates. Our results show that end-to-end deep learning is compatible with tasks performed by conventional GCMs and can enhance the large-scale physical simulations that are essential for understanding and predicting the Earth system.

Solving the equations for Earth's atmosphere with general circulation models (GCMs) is the basis of weather and climate prediction<sup>1,2</sup>. Over the past 70 years, GCMs have been steadily improved with better numerical methods and more detailed physical models, while exploiting faster computers to run at higher resolution. Inside GCMs, the unresolved physical processes such as clouds, radiation and precipitation are represented by semi-empirical parameterizations. Tuning GCMs to match historical data remains a manual process<sup>3</sup>, and GCMs retain many persistent errors and biases<sup>5–8</sup>. The difficulty of reducing uncertainty in long-term climate projections<sup>9</sup> and estimating distributions of extreme weather events<sup>10</sup> presents major challenges for climate mitigation and adaptation<sup>11</sup>.

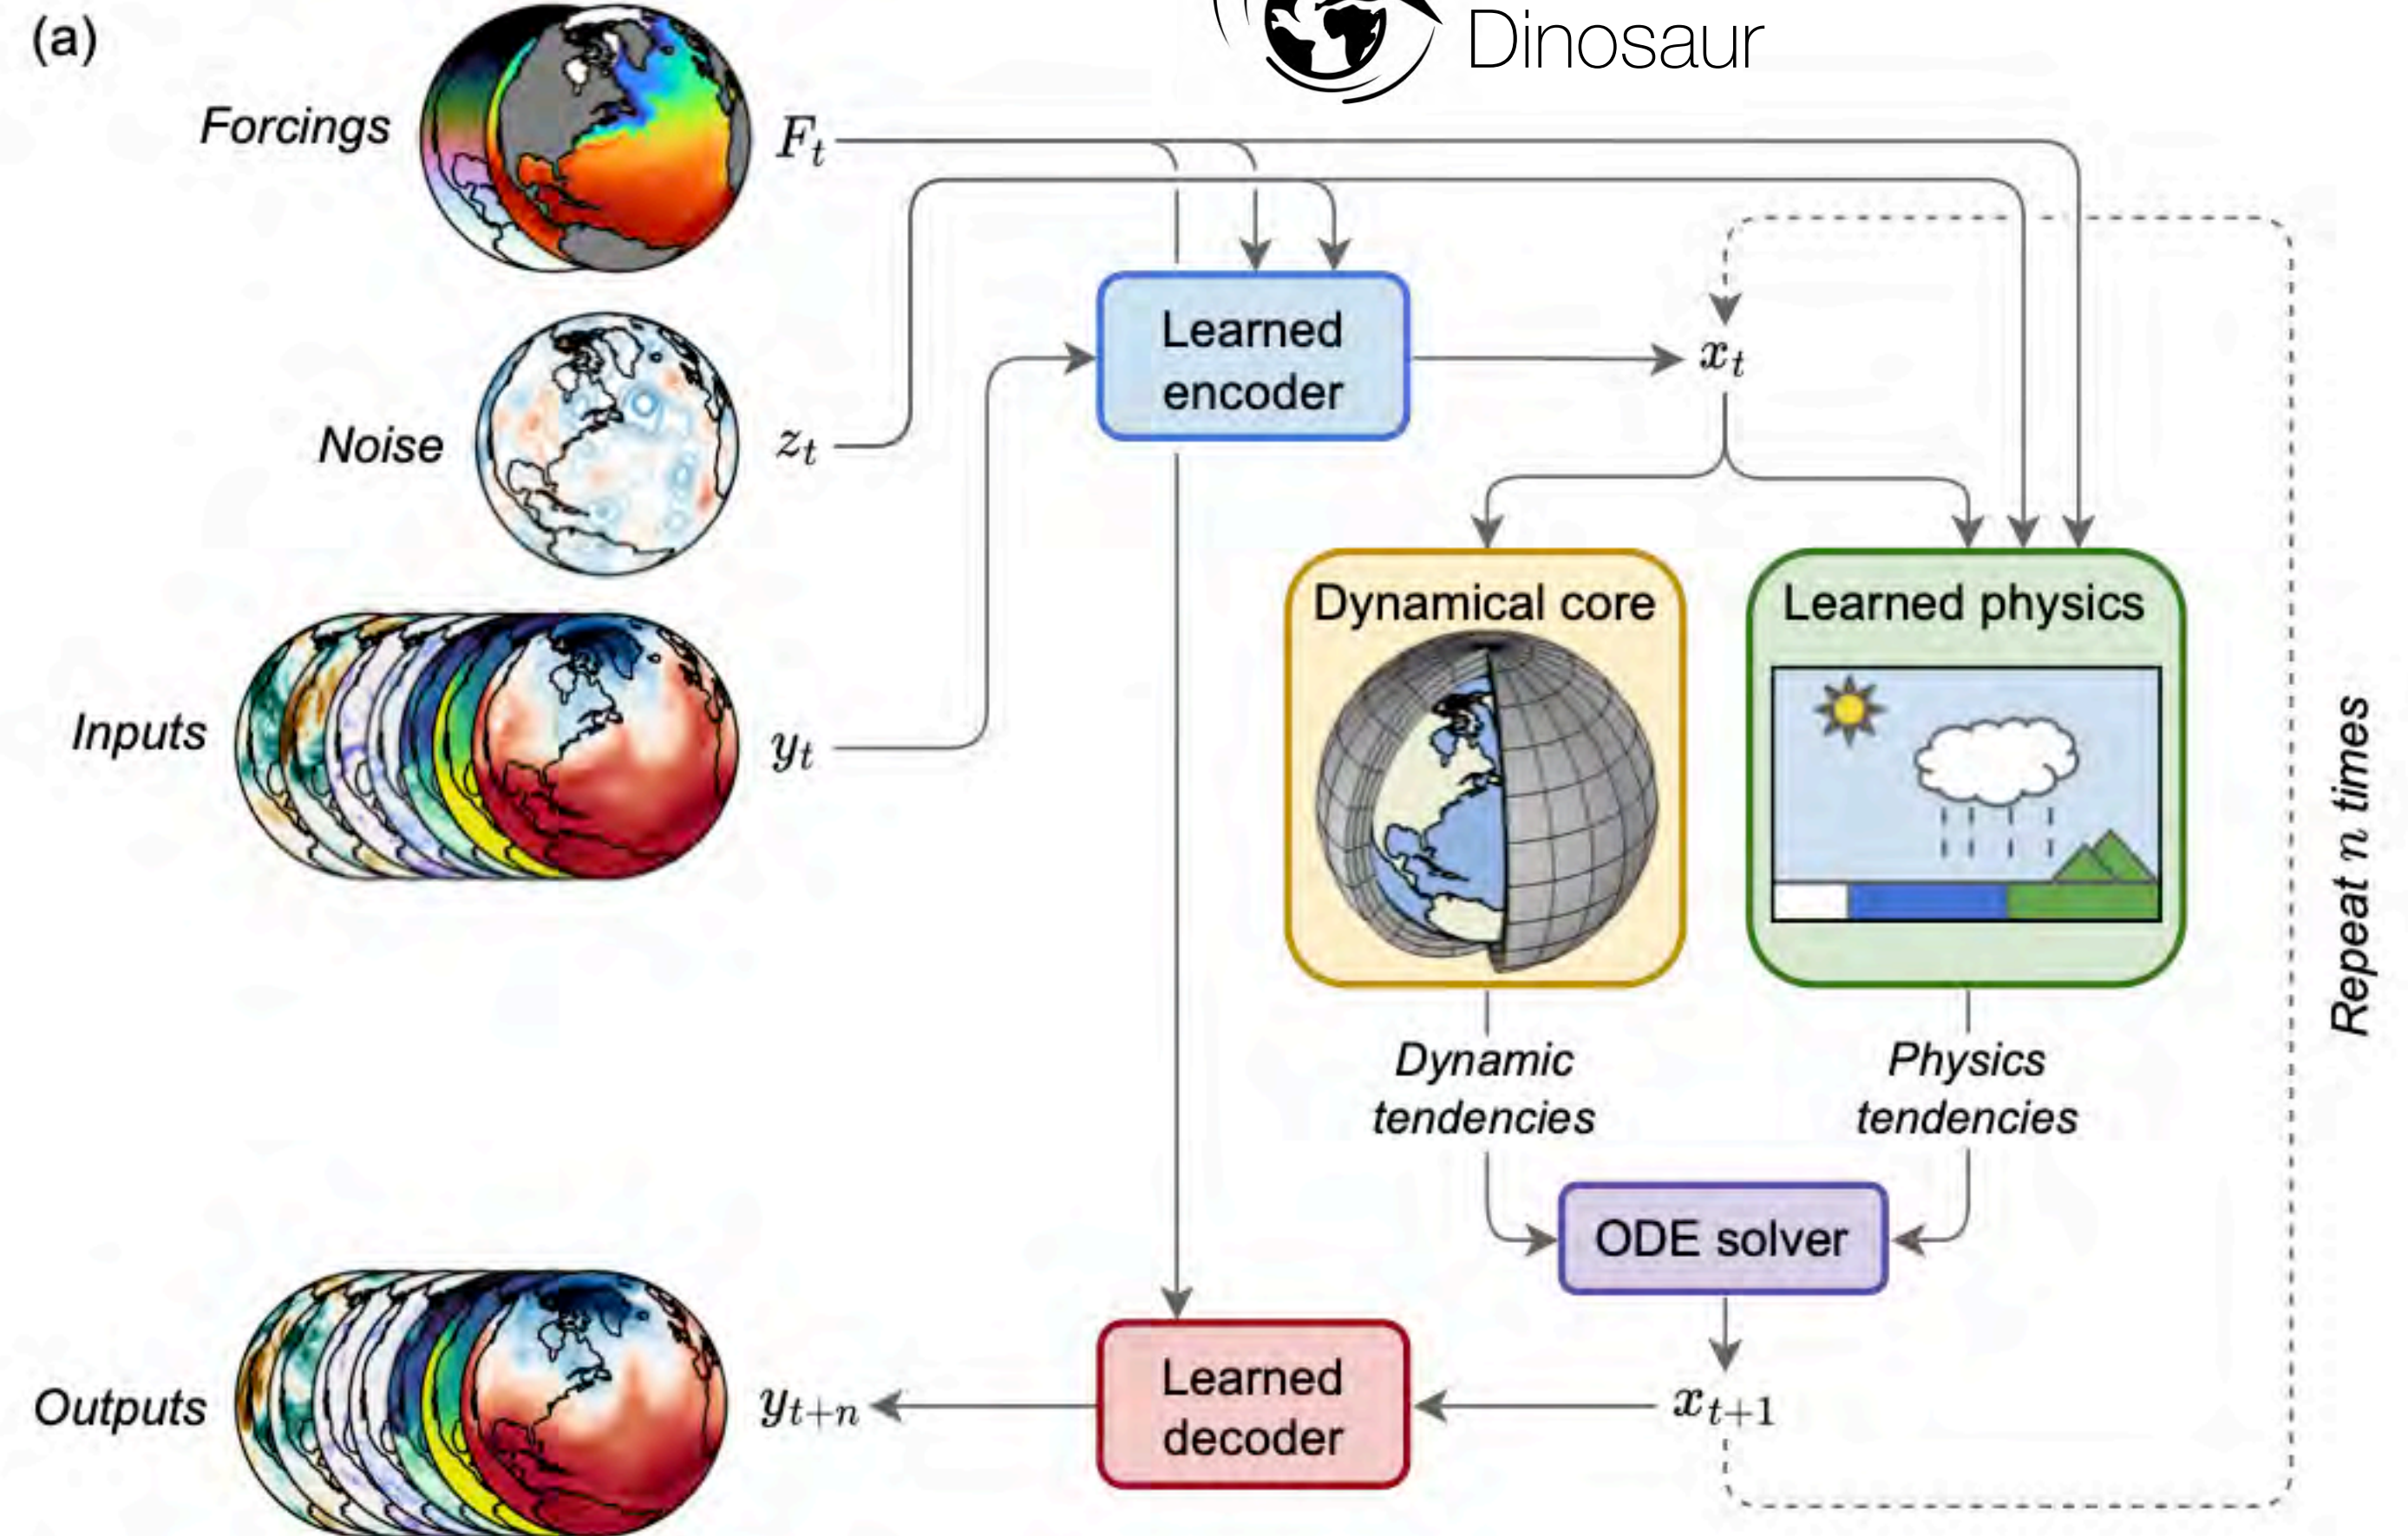

Recent advances in machine learning have presented an alternative for weather forecasting<sup>3,4,12,13</sup>. These models rely solely on machine-learning techniques, using roughly 40 years of historical data from the European Centre for Medium-Range Weather Forecasts (ECMWF) reanalysis v5 (ERAS)<sup>14</sup> for model training and forecast initialization. Machine-learning methods have been remarkably successful,

demonstrating state-of-the-art deterministic forecasts for 1- to 10-day weather prediction at a fraction of the computational cost of traditional models<sup>3,4</sup>. Machine-learning atmospheric models also require considerably less code, for example GraphCast<sup>3</sup> has 5,417 lines versus 376,578 lines for the National Oceanic and Atmospheric Administration's FV3 atmospheric model<sup>15</sup> (see Supplementary Information section A for details).

Nevertheless, machine-learning approaches have noteworthy limitations compared with GCMs. Existing machine-learning models have focused on deterministic prediction, and surpass deterministic numerical weather prediction in terms of the aggregate metrics for which they are trained<sup>3,4</sup>. However, they do not produce calibrated uncertainty estimates<sup>4</sup>, which is essential for useful weather forecasts<sup>1</sup>. Deterministic machine-learning models using a mean-squared-error loss are rewarded for averaging over uncertainty, producing unrealistically blurry predictions when optimized for multi-day forecasts<sup>3,13</sup>. Unlike physical models, machine-learning models misrepresent derived (diagnostic) variables such as geostrophic wind<sup>16</sup>. Furthermore,

ERA5

NeuralGCM

**Hybrid w/ online : non-blurry forecast + stable simulators (runs ~10 years)**

# Summary

- Illustrated why we are **augmenting models** with ML

- Described how this can be **done in practice** today

- Advocated that a **deep recast** of our models is needed

- Described upcoming **AI-native hybrid** models

- Exciting time for **cross-disciplinary** investigations !
